- As one of the most fundamental problems in statistics, robust location
- 2 estimation has many prominent solutions, such as the trimmed mean,
- 3 Winsorized mean, Hodges-Lehmann estimator, Huber M-estimator,
- 4 and median of means. Recent studies suggest that their maximum
- 5 biases concerning the mean can be quite different, but the underlying
- 6 mechanisms and average performance remain largely unclear. In this
- article, similar to the mean-median-mode inequality, it is proven that
- 8 in the context of nearly all common unimodal distributions, there
- 9 exists an orderliness of symmetric quantile averages with different
- 10 breakdown points. Further deductions explain why the Winsorized
- mean and median of means generally have smaller biases compared
- $_{12}$ to the trimmed mean. Building on the U-orderliness, the superiority
- of the median Hodges-Lehmann mean is discussed.
